The rechargeable C cell I mentioned above (1.2v, 2.2Ah) holds 9,500 joules. A capacitor holding this much energy at 1.2v would have to be $(2 \times 9,500 / 1.2 \times 1.2) = 13,000$ Farads, so if it helps, you can think of a battery as an enormous capacitor. Energy stored in a real capacitor - the earth!

Capacitors used for energy storage. Capacitors are devices which store electrical energy in the form of electrical charge accumulated on their plates. When a capacitor is connected to a power source, it accumulates energy which can be released when the capacitor is disconnected from the charging source, and in this respect they are similar to batteries.

This reveals a major disadvantage of capacitors as energy storage devices - the stored energy for a given size is very low, a battery of the same size would have at least a thousand times more stored energy! However, caps have greatly lower internal resistances than chemical batteries, which enable them to dump all their stored energy quickly.

While batteries and capacitors are both energy storage devices, they differ in some key aspects. A capacitor utilizes an electric field to store its potential energy, while a battery stores its energy in chemical form. Battery technology offers higher energy densities, allowing them to store more energy per unit weight than capacitors.
