5. CONCLUSION AND FUTURE WORK In this paper we have concluded that using state space method we can easily find the response and stability of the RLC circuit and also with the help of MATLAB the analysis of an RLC circuit becomes too simpler.

What are the energy storage elements in RLC circuit?

There are two independent energy storages in RLC circuit, the capacitor which stores energy in an electric field and the inductor which stores energy in a magnetic field. The state variables are the energy storage variables of these two elements,  $V_C$  and  $i_L$ . The energy storage elements of a system are what make the system dynamic.

What are LC circuits with external DC excitations?

LC circuits with external DC excitations. Transients are generated in Electrical circuits due to abrupt changes in the operating conditions when energy storage elements like Inductors or capacitors are present. Transient response is the dynamic response during the initial phase before the steady state response is achieved.

How do you find the initial condition of a circuit?

To obtain the initial condition, the circuit at instant  $t = 0^+$  will be used, which is obtained from that in Fig. 1.96, substituting the capacitor for a voltage source of value  $V_C(0^+)$ . Except for an impulse-type response: The circuit at time  $t = 0^+$  is shown in Fig. 1.97.

In general, the order of the input-output differential equation will be the same as the number of independent energy storage elements in the system. Independent energy storage cannot be combined with other energy storage elements to form a single equivalent energy storage element.
