

Are phase change materials suitable for thermal energy storage?

Phase change materials (PCMs) having a large latent heat during solid-liquid phase transition are promising for thermal energy storage applications. However, the relatively low thermal conductivity of the majority of promising PCMs ($< 10 \text{ W/(m} \cdot \text{K)}$) limits the power density and overall storage efficiency.

Why is phase change energy storage a non-stationary process?

During the phase change process, the temperature of PCM remains stable, while the liquid phase rate will change continuously, which implies that phase change energy storage is a non-stationary process. Additionally, the heat storage/release of the phase change energy storage process proceeds in a very short time.

Why are phase change materials difficult to design?

Phase change materials (PCMs), which are commonly used in thermal energy storage applications, are difficult to design because they require excellent energy density and thermal transport, both of which are difficult to predict from simple physics-based models.
