As we saw in the previous tutorial, in a RC Discharging Circuit the time constant (t) is still equal to the value of 63%. Then for a RC discharging circuit that is initially fully charged, the voltage across the capacitor after one time constant, 1T, has dropped by 63% of its initial value which is 1 - 0.63 = 0.37 or 37% of its final value. Thus the time constant of the circuit is given as ...

When the short is opened, the stored energy is transferred in part or totally to a load by lowering the current of the coil via negative voltage (positive voltage charges the magnet). The Superconducting Magnetic Energy Storage (SMES) is thus a current source [2, 3]. It is the "dual" of a capacitor, which is a voltage source.

A capacitor is a device that stores electrical charge. The simplest capacitor is the parallel plates capacitor, which holds two opposite charges that create a uniform electric field between the plates.. Therefore, the energy in a capacitor comes from the potential difference between the charges on its plates.
