

Flywheel energy storage (FES) works by accelerating a rotor (flywheel) to a very high speed and maintaining the energy in the system as rotational energy. The energy is converted back by slowing down the flywheel. Most FES systems use electricity to accelerate and decelerate the flywheel, but devices that directly use mechanical energy are being developed.

The cost invested in the storage of energy can be levied off in many ways such as (1) by charging consumers for energy consumed; (2) increased profit from more energy produced; (3) income increased by improved assistance; (4) reduced charge of demand; (5) control over losses, and (6) more revenue to be collected from renewable sources of energy ...

Flywheel energy storage From Wikipedia, the free encyclopedia Flywheel energy storage (FES) works by accelerating a rotor ... When used in vehicles, flywheels also act as gyroscopes, since their angular momentum is typically of a similar order of magnitude as the forces acting on the moving vehicle. This property may be detrimental

They have high efficiency and can work in a large range of temperatures [4] and can reduce the ramping of conventional

The flywheel that was used was rather large (160 cm diameter) and heavy (1.5 ton) and was enclosed inside an airtight chamber filled with hydrogen gas at reduced pressure to lower resistance. Recharging the flywheel from standstill took up to 40 minutes, but once spun, adding additional energy to the flywheel took as little as two to five minutes.
