The moment of inertia plays a crucial role in this process, affecting how much energy a flywheel can store. The energy stored by a rotating flywheel can be calculated using: $E = \frac{1}{2} I \omega^2$ Where: E is the kinetic energy in joules. I is the moment of inertia in kg m². ω (omega) is the angular velocity in rad/s.

While a single flywheel device has a typical capacity on the order of kilowatts, many flywheels can be connected in a "flywheel farm" to create a storage facility on the order of megawatts.

Meaning that a flywheel with 1 kg and occupying about half litre could store the energy needed to bring a car moving at 100 Km/h to a standstill. Depending on how hard the brakes are stepped on, this energy can be produced in just a handful of seconds. If it takes 10 seconds, average power output of such braking will be 36 kW.
